2018. After 18 years of investigation to establish the cause of thousands of military personnel deaths, this Italian parliamentary commission found a statistically significant association between the administration of combined and multi-dose vaccines, according to the military prophylactic vaccination schedule, and the development of tumours and autoimmune diseases. (page 156 of the report). N.B. The same vaccines are recommended for military personnel as are recommended for children (pp. 156-157). The commission was unable to find a single study proving that combined vaccines are safe (page 154). The Commission estimated that "the cumulative amount of the various components of the vaccines exceeds the permitted limit for the marketing authorisation of the single vaccine."
